HLD: Distributed Caching

"Concept && Coding" YT Video Notes

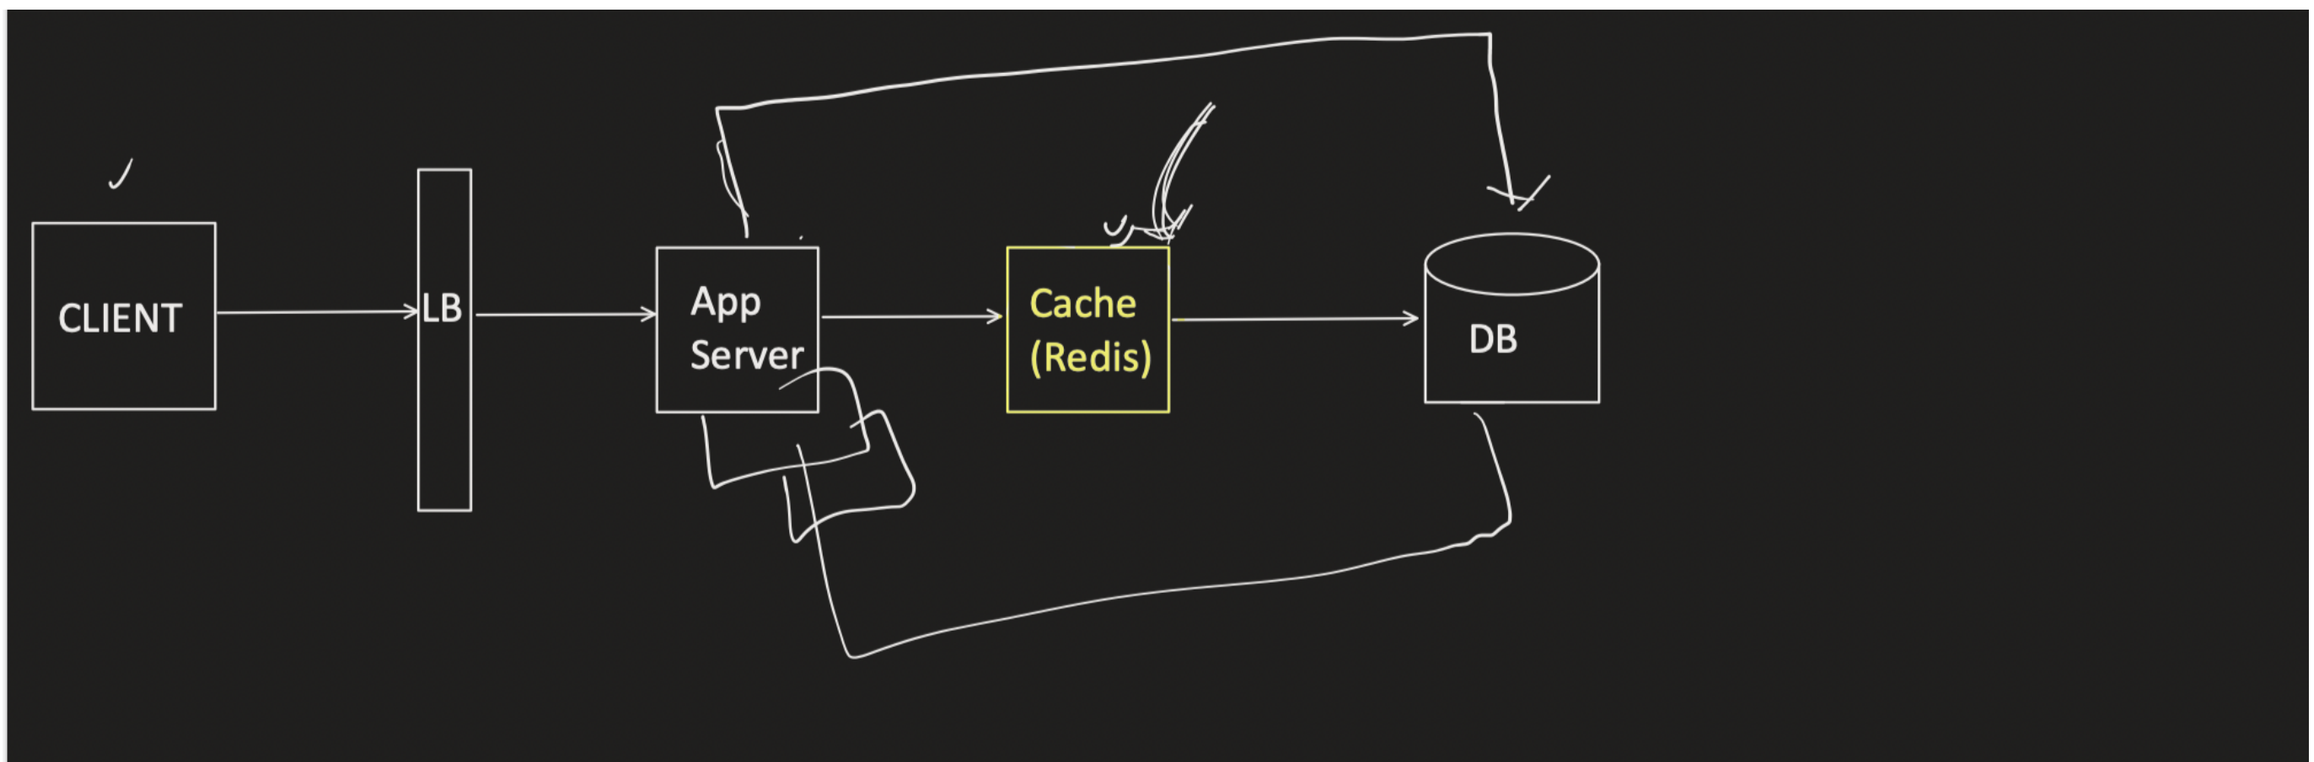

What is Caching?

- Caching is a technique to store frequently used data in a fast access memory rather than accessing data every time from slow access memory.
- This makes our system very fast.
- It helps to reduce the latency.
- It also helps to achieve the fault tolerance.

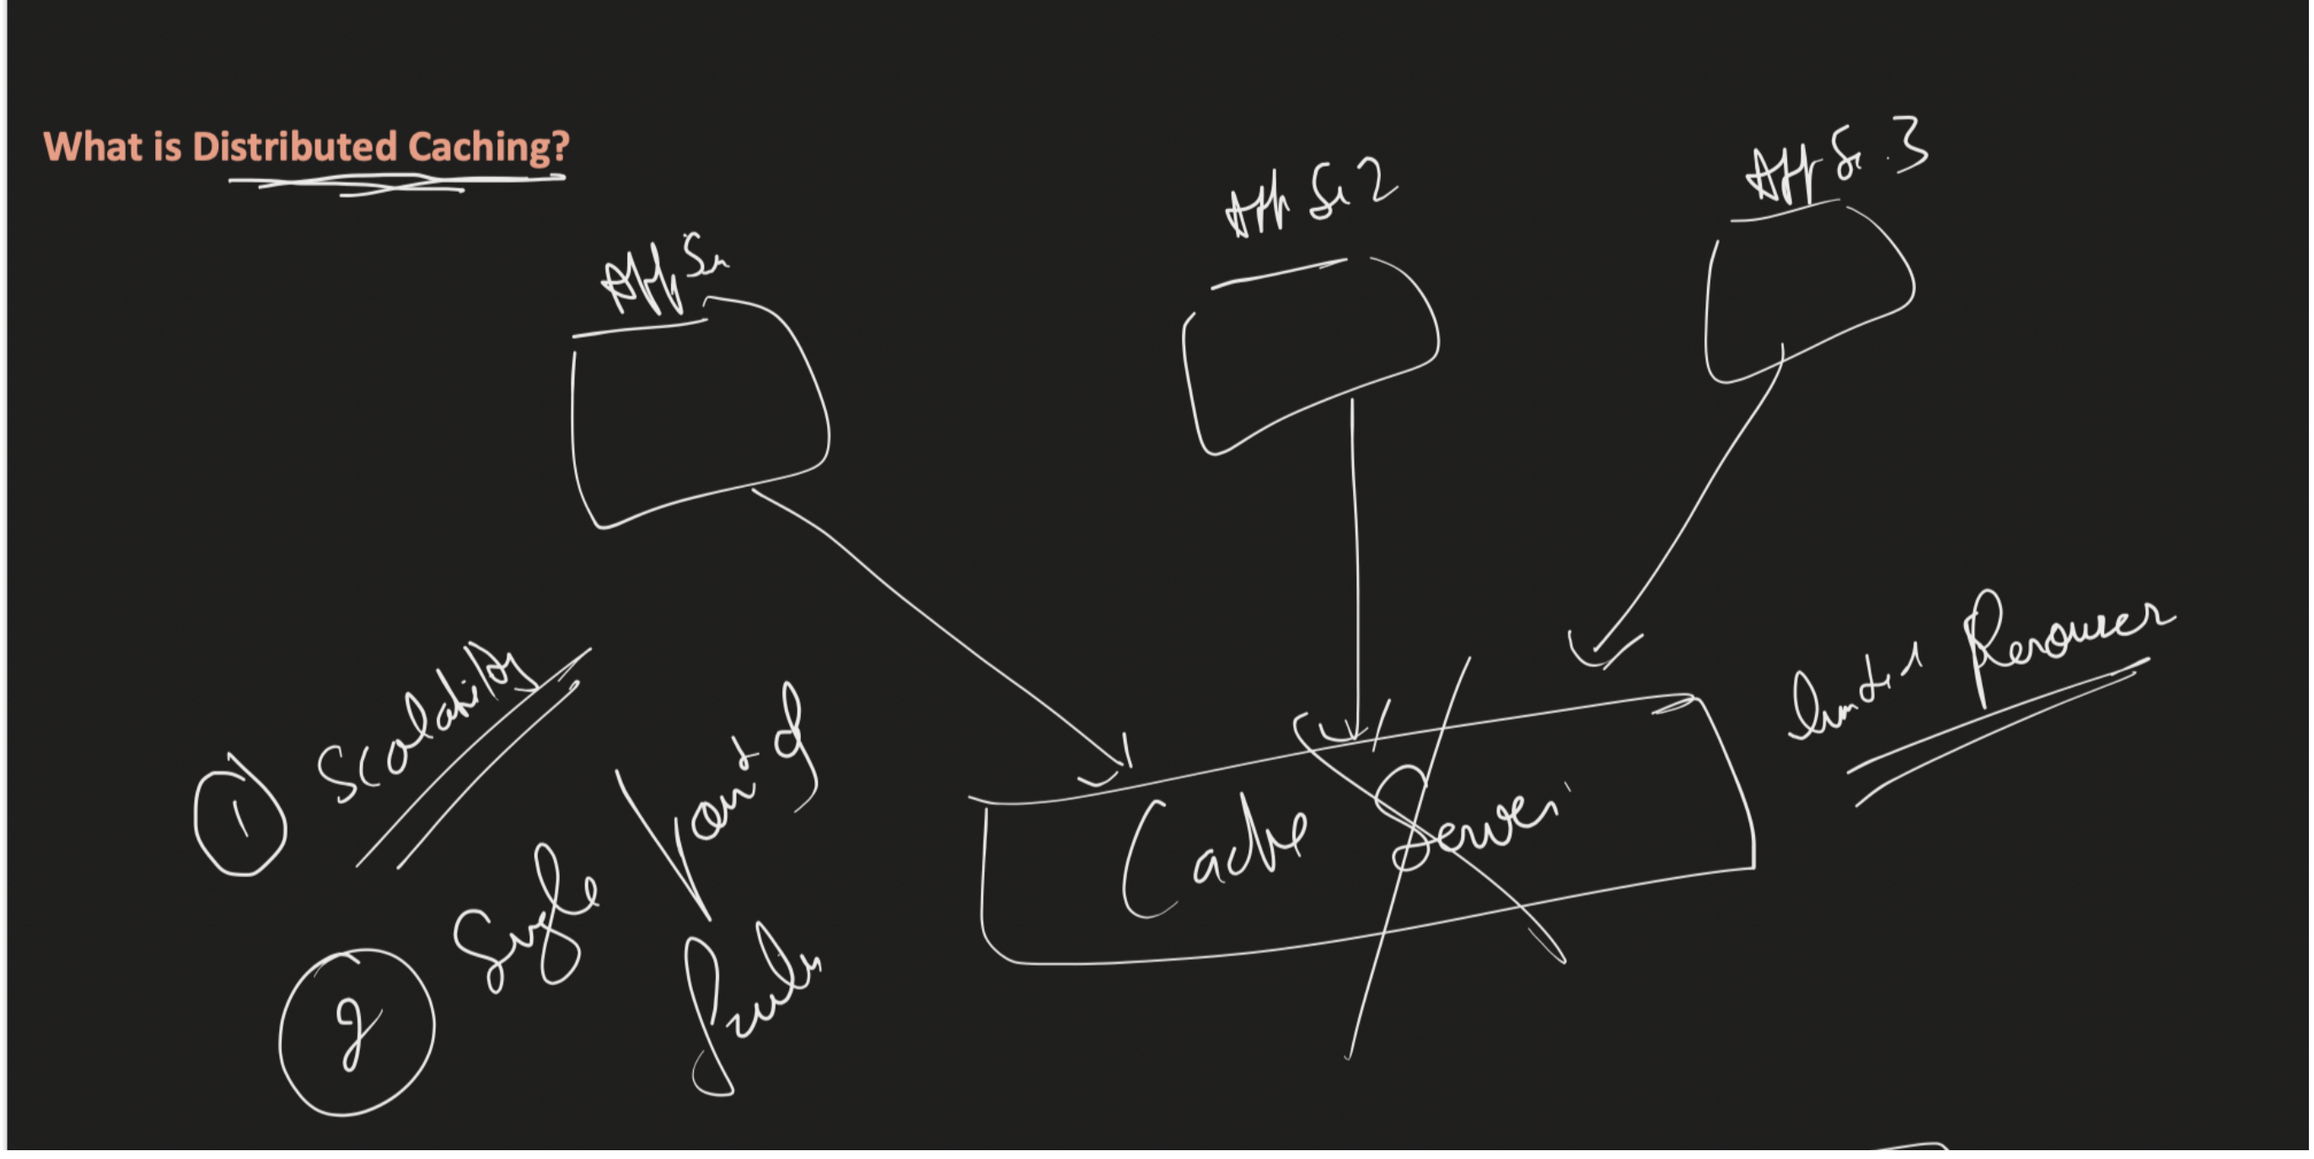

There are different types of caching present at different layer of the system Like:

- Client side Caching (Browser Caching)
- CDN (used to store the static data)
- Load Balancer
- **Server Side Application Caching (like Redis etc.)**

etc.
